Abstract
We have synthesized a new and stable MR contrast agent, SPIO-mPEG-cRGD, that exhibits superior binding to the biologic target αvβ3 integrins. Selective targeting of αvβ3 integrins was achieved by conjugating cyclic RGD peptides to the superparamagnetic iron oxide nanoparticles (SPIO) surface, while poly(ethylene glycol) (PEG) was used for nonimmunogenic, nonantigenic and protein resistant. The signal intensity of positive-cell tumor was significantly lower than that of negative-cell tumor from pre-contrast to post-contrast images of the tumor. Internalization of SPIO-mPEG-cRGD into targeted cells were observed by in vitro and in vivo MR imaging studies.

Introduction
Molecular Imaging has recently been developed very rapidly and extensively in biotechnology [1]. Tumor-targeted drug delivery can enhance the effectiveness of chemotherapeutics while decreasing the systemic toxicity of these drugs. Iron oxide nanoparticles for MR imaging are often coated with poly(ethylene glycol) (PEG), which itself has been frequently used as a drug carrier because of its biocompatibility, water solubility nonimmunogenic, nonantigenic and protein resistant. There are some reports that macromolecules conjugated with cRGD peptides, were successfully recognized by αvβ3 integrins receptor and internalized into cells via αvβ3 integrin receptor-mediated endocytosis [2, 3]. In this study, we synthesized a new T₂-weighted contrast agent which has nanometer-size, hydrophilic, long-circulating PEG-coated and characterized SPIO particles that were tethered to cRGD (SPIO-mPEG-cRGD).

Methods
We test various cell lines with different levels of αvβ3 integrin over-expression: MCF-7, HT-29, A549 and HT1080. In addition, KB cell line was chosen as negative cell which low-expression αvβ3 integrin receptors. All cells were incubated with SPIO-mPEG-cRGD nanoparticles (0.3 mM Fe), washed by PBS buffer and scanned by 3.0 T MRI. Five nude mice (5 weeks old, female) were subcutaneous injected A549 and KB cells to the left and right lateral thigh of mice. MRI experiment was performed two weeks after tumor implantation, at which time the tumors were measured to be at least 0.5 cm in diameter. This method produces a high yield of tumor in the lateral thighs of nude mice.

Results and Discussion
SPIO-mPEG-cRGD nanoparticles were synthesized and characterized by DLS, FT-IR, 20 MHz relaxometer, NMR, SQUID, TGA, and TEM. Before cRGD peptide was conjugated with SPIO nanoparticles, we pre-modified the surfaces of SPIO nanoparticles to improve the affinity of cRGD conjugating to the particles. Above all, the SPIO nanoparticles were synthesized by pyrolysis ferric-oleate complexes and coated oleic acid around the surface. And then the surface hydrophobic oleate of SPIO was replaced by hydrophilic mPEG derivative, mPPDA-silane. According to thiol-disulfur bond exchange reaction, SPIO-mPPDA was covalently coupled to cRGD. The conjugation products were characterized by DLS, FT-IR, 20 MHz relaxometer, NMR, SQUID, TGA, and TEM. The SPIO-mPPDA-cRGD nanoparticles were synthesized and characterized by DLS, FT-IR, 20 MHz relaxometer, NMR, SQUID, TGA, and TEM.

Conclusion
We have successfully prepared and characterized biocompatible superparamagnetic SPIO-mPEG-cRGD. They are hydrophilic, weakly cell-cytotoxic, and well-dispersed under physiological conditions. Moreover, SPIO-mPEG-cRGD have the ability to target and differentiate human cancer cells with αvβ3 integrin expression such as MCF-7, HT-29, A549 and HT1080 tumors as proven by both in vitro and in vivo MR imaging studies. Therefore, SPIO-mPEG-cRGD can be potentially used as an MRI contrast agent for the detection of αvβ3 integrin expression cancers.
