Purpose: To assess the value of magnetic resonance (MR) diffusion-weighted imaging (DWI) in the evaluation of deep infiltrating endometriosis (DIE).

Materials and Methods: In a prospective single center study, DWI was added to the standard MR imaging protocol in 56 consecutive patients with known or suspected endometriosis. Endometriotic lesions as well as (functional) ovarian cysts were analysed for location, size, and signal intensity on T1-, T2-, and DWI. Signal intensity ratios were calculated, using the obturatorius muscle. Apparent diffusion coefficient (ADC) values were calculated using b-values of 50, 400, 800 and 1200 s/mm². Statistical analysis included the Spearman correlation coefficient, Mann Whitney U and Kruskall-Wallis tests.

Results: A total of 112 lesions (62 endometrial cysts and 48 DIE) were detected, 60 of which were large enough to analyse. Mean ADC values of endometrial cysts (2.14 x 10⁻³/mm²/s) were significantly lower than ADC values of functional ovarian cysts (1.11 x 10⁻³/mm²/s; p<0.001). Mean ADC values of DIE retrocervical, infiltrating the colon and bladder were 0.70 x 10⁻³/mm²/s, 0.79 x 10⁻³/mm²/s and 0.76 x 10⁻³/mm²/s respectively. ADC values of DIE did not show a significant difference between varying pelvic locations (p=0.63). Moreover we found a highly significant correlation between ADC values and T2SI ratios in endometrial cysts (r=0.77; p<0.001).

Conclusion: Results of our study suggest that ADC values of DIE are consistently low, without significant difference between pelvic locations. In addition, in the differentiation between endometrial cysts from other pelvic cysts, ADC values show a comparable diagnostic performance as evaluation of the T2- and T1-weighted images.
