Introduction: Non-linear local gradients for MRI have been introduced \cite{1} with the aim to overcome present limitations of gradient performance due to safety limitations from peripheral nerve stimulation (PNS) and to investigate novel non-linear encoding strategies. The PatLoc (parallel acquisition technique using localized gradients) fields used so far have been quadrupolar spherical harmonics \cite{2}. Here we present a concept study of a planar gradient system for body applications. This gradient system intended for imaging of heart, abdomen and pelvis will be implemented in our 3T whole-body scanner equipped with 6 gradient channels.

Materials and Methods: The coil size is chosen to fit into the patient table of a Siemens 3T Tim Trio (Siemens Medical Solutions, Erlangen, Germany). The size is therefore limited to $0.49 \times 0.05 \times 1.69$ m. This non-shielded PatLoc gradient coil system will consist of 3 channels (channel 1, channel 2 and channel 3). Each channel is built up of 2 to 4 coil elements and will be wound of $2.7$ mm insulated copper wire. Magnetic field simulations were performed with Matlab (Mathworks, Natick, USA) in a region of 1 cubic meter with a resolution of 100 voxels in each direction.

Results and Discussion: The size of the inner coil elements of channel 1 and channel 2 is $0.141 \times 0.331$ m. Channel 3 consists of 2 coil elements which have a dimension of $0.401 \times 0.241$ m. The outer coil elements of channel 1 and channel 2 have a dimension of $0.141 \times 0.201$ m. They are used to balance torques and forces. Channel 3 is intrinsically balanced. A 3D region of interest (ROI) of $0.5 \times 0.5 \times 0.5$ m, for later image acquisition, was chosen. Fig 2 displays contour lines of the $B_z$ component of the magnetic field from an xz plane at $y=0.24$m generated by the different channels of the coil.

The overlay of contour lines of two fields represent effective local voxel shapes achievable when these two fields are used for encoding. Fig 2 i) shows that the resulting fields from channel 1 and 2 generate nearly rectangular voxels around the center of the ROI. In a number of situations, however, the local field gradients become parallel to each other or too weak, which would limit the FOV achievable. The fields of channel 3 were designed in a way to complement the channels 1 and 2, such that in regions where gradients of channel 1 and 2 are parallel, channel 3 produces an approximately orthogonal gradient. This is visualized in Fig 2 ii) and iii). The contour plots in Fig 2 suggest that through the combination of the 3 gradient channels it might be possible to cover the whole ROI with voxels closely approximating rectangular shapes.

Channel 1 and 2 have identical electrical characteristics with resistance of $107\text{m}$$\Omega$ and inductance of $218\mu$H and a total length of 38m. Channel 3 has resistance of $118\text{m}$$\Omega$, inductance of $219\mu$H and a total length of 33.1m. Channel 1 and 2 are designed to be driven with up to 100A. Due to its higher sensitivity, channel 3 is driven with up to 40A.

Simulations of image reconstruction from data encoding used this coil design were performed. 6 RF coil-profiles were simulated to approximate a body receive array. 2D imaging with 3 gradient channels can be performed with a variety of different encoding trajectories \cite{3,4}. As a simple demonstration that useful images can be obtained with this design we concatenated three 64 $\times$ 64 2D Cartesian trajectories, one for each pairwise permutation of the 3 gradient channels. The resolution of the object simulated was $256 \times 256$ pixels. The reconstructed images with a resolution of $128 \times 128$ pixels of the abdominal region and of a checkerboard pattern can be seen in Fig 3 alongside the original simulated object. For the reconstruction 15 conjugate gradient iterations were performed. The images demonstrate reasonable spatial resolution over the entire FOV even at locations where some of the encoding fields flatten out and provide no encoding.

Conclusions: A balanced planar gradient system is designed which achieves extended FOV for 2D imaging by combining three of its channels. Availability of such a gradient system will open new perspectives for flexible region-specific encoding in different body regions.
