Target Audience: MR physicists, engineers.

Purpose: B_1 mapping methods based on the Bloch-Siegert (BS) effect have traditionally used large frequency offsets \( \omega_{RF} \) for the BS irradiation pulse to minimize sensitivity to off-resonance and direct excitation of magnetization by this pulse. In addition, the use of large \( \omega_{RF} \) facilitates \( B_1 \) calculation since it allows linear approximation of BS frequency shift as function of \( B_1 \). However, it may be possible to improve on \( B_1 \) mapping performance by reducing \( \omega_{RF} \) and correcting for the negative side effects mentioned above. To investigate this, we performed theoretical analysis of the BS mapping technique without restricting \( \omega_{RF} \). Based on this, we demonstrate that with some sequence modifications, the BS-based sequence can be applied far beyond the regime of offsets original defined to achieve lower RF power deposition and better SNR efficiency. Finally, for a gradient-echo (GRE) based BS mapping sequence, the effect of sequence parameters on SNR at a given SAR level is studied. The theoretical findings were then confirmed with studies of human brain at 7T.

Methods: For the BS phase shift \( \phi_{BS} \) acquired with dual constant frequency offset \( \pm \omega_{RF} \), under linear approximation \( (|\omega_{RF}|<\omega_{RF}) \), it can be shown that \( \phi_{BS}/\omega_{RF} \propto \text{SNR}_{SNR}/\text{SNR}_{SAR} \). This suggests reducing \( \omega_{RF} \) to increase the energy efficiency of BS methods. Three adverse effects of reducing \( \omega_{RF} \) can be corrected with additional sequence modifications. Increased sensitivity to \( B_1 \) inhomogeneity can be corrected with integrated \( B_1 \) mapping (reproduced from the reference) (Fig.1). The other two modifications are provided in the following.

Correcting Direct Excitation and Imaging Flip Angle (FA) Dependency: Artifacts related to the direct excitation effect may be suppressed by sufficient crusher gradients, which should be optimized given the non-selective nature of the BS pulse. In addition, it can be derived from Bloch equations that with sufficient crushers, the BS shift does not depend on FA if FA>0. In other words, sufficient crusher pair reduces the sensitivity to actual slice profiles and steady state effects, and FA can be simply selected as Ernst angle, a very nice feature in practice.

Overdriving: If the condition \(|\omega_{RF}|<\omega_{RF} \) is lifted, mapping efficiency can be further improved. But the linear approximation is no longer valid. This makes derivation of analytical equations very hard. In the following, we will refer to this situation as “overdriven” BS mapping, or OBS mapping. Signal evolution during OBS mapping was studied by simulations of the Bloch equations. For our sequence (Fig. 1) \( \omega_{RF}=500Hz \) was used. Fig.2a shows how \( \phi_{BS} \) changes as a function of \( B_1 \) for the hard pulse (red), Fermi pulse (green), and the optimized pulse (blue, “QDAPX”). The figure shows that with sufficient crushers, over a large range of \( B_1 \), \( \phi_{BS} \) continues to increase with \( B_1 \), although at high \( B_1 \), depending on the pulse shape, different degrees of oscillation can be observed. The QDAPX pulse was chosen for further optimizations given its robustness in \( B_1 \) estimation in the presence of noise in \( \phi_{BS} \). To optimize the sequence parameters (such as imaging flip angle and repetition time TR) at a constant SAR level, both the SNR and the SAR level acquired in a volunteer study were used to calibrate the simulation parameters. In addition, for each simulation, the steady state magnetization level was computed (\( T_1 \) was assumed to be 1.5 seconds). Angle-to-Noise Ratio (ANR) efficiency, i.e. mapping sensitivity, was determined from the calculated \( \phi_{BS} \), divided by the thermal noise level and the square root of the scan time. Simulation results for various imaging flip angles at a given SAR level (100%) (Fig.2b) show that for a specific SAR level, optimal ANR is achieved at long TR; furthermore, at a specific TR value, ANR is optimal when using imaging flip angles close to the Ernst angle.

Results and Discussion: The effectiveness of the proposed sequence was demonstrated with IRB approved volunteer studies. All experiments were performed on a Siemens Magnetom 7T (Erlangen, Germany) scanner based on an Agilent 7T-830-AS (Oxford, UK) magnet, with a 32-channel head coil (Nova Medical Inc., Wilmington, MA, USA). Common imaging parameters were: FOV 256mm, imaging matrix 64x64, slice thickness=5mm, and BS pulse duration=8ms. The reference \( B_1 \) map was acquired with a 2kHz Fermi pulse (nominal \( \phi_{BS}=70^\circ \), TR = 844ms, 10 averages). OBS \( B_1 \) mapping (Fig.3) with \( \phi_{BS}/\omega_{RF}=1.54 \) and \( \phi_{BS}/\omega_{RF}=0.37 \), TR=500ms, TE=[15,16]ms, 45\(^\circ\) imaging flip angle, single repetition, and maximum allowable SAR level. The \( B_1 \) map acquired with OBS has an RMSE of 0.57% whereas the one acquired under linear assumption has a RMSE of 3.01%, comparable to that achieved in recent studies, but about 5-fold larger than the RMSE acquired under the overdriven condition. The ANR advantage of OBS is illustrated in Fig. 4. Comparison of an OBS sequence with a traditional BS sequence used at identical TR, TE, and imaging flip angle shows ANR efficiencies of 69.25 and 81.11 respectively (OBS: \( \phi_{BS}=500Hz \), QDAPX pulse, 64% maximum SAR level, BS: \( \phi_{BS}=8kHz \), Fermi pulse, 93% maximum SAR level). The OBS sequence achieved at least 8-fold improvement in ANR with 30% lower RF energy deposition than the BS mapping under conventional conditions. Even for the OBS sequence with much shorter TR (140ms rather than 1s) at 64% SAR, the average ANR efficiency is still about 2.5 times higher than the traditional Fermi based sequence at 93% SAR.

Conclusion: Reducing the off-resonance frequency of the irradiation pulse in BS-based \( B_1 \) mapping allows improved mapping efficiency and speed. Potential detrimental effects of this approach on \( B_1 \) mapping accuracy can be mitigated by modifications to the acquisition technique and to the theoretical model used for the \( B_1 \) calculation. As a result, improved \( B_1 \) accuracy can be achieved for given scan time and SAR, as was demonstrated in human studies.
