Target Audience: Scientists and clinicians interested in hyperpolarized gas magnetic resonance imaging (MRI).

Purpose: Previous work using hyperpolarized helium-3 ($^3$He) MRI provides a strong foundation for the use of MRI in asthma research and patient care, however, a major drawback has been that we do not clearly understand the etiology of MRI-derived ventilation defects. We hypothesize that in asthma, $^3$He MRI ventilation abnormalities are related to airways that are remodeled and/or constricted. Therefore, in this proof of concept study, in a small group of asthmatic and healthy subjects, we quantitatively evaluated the relationship between hyperpolarized $^3$He MRI ventilation abnormalities and multi-detector x-ray computed tomography (MDCT) airway measurements in a region-of-interest (ROI) spatially identified by $^3$He MRI to contain ventilation defects.

Methods:

Subjects: Asthmatic and healthy subjects provided written informed consent to the study protocol approved by the local research ethics board and performed spirometry, plethysmography, MRI and MDCT. Subjects were enrolled between the ages of 18-60 years, with baseline forced expiratory volume in one second (FEV$_1$) > 60%pred.

Image Acquisition: MRI was performed on a whole body 3.0 Tesla Discovery 750 scanner (General Electric Health Care, Milwaukee, WI, USA) in the coronal plane, as previously described (1). For $^3$He MRI static ventilation images, a fast gradient-recalled echo sequence was used (14 s breath hold; repetition time (TR) = 4.3 ms; echo time (TE) = 1.4 ms; flip angle = 7 degrees; field of view = 40 x 40 cm; matrix, 128 x 128; 14-17 slices; slice thickness = 15 mm; 0 mm gap). $^3$He gas was provided by a turn-key, spin-exchange polarizer system (HelSpin, General Electric Health Care, Durham, NC, USA), with images acquired in breath-hold after inspiration of a 1 L $^3$He/N$_2$ mixture from functional residual capacity (FRC). $^3$He MRI was acquired at a similar lung volume using a fast spoiled gradient echo sequence (16 s breath-hold; TR = 4.7 ms; TE = 1.2 ms; flip angle = 30 degrees; field of view = 40 x 40 cm; matrix, 128 x 128; 14-17 slices; 15 mm slice thickness; 0 mm gap). Following $^3$He MRI, thoracic CT was performed using a 64-slice Lightspeed VCT scanner (GE Healthcare, Milwaukee, WI USA) using a detector configuration of 64x0.625 mm, 120 kVp, 100 effective mA, tube rotation time of 500 ms and a pitch of 1.0. In order to reduce the radiation dose delivered to each subject, CT images were acquired for 56 (versus a total of 400 possible) 1.25 mm thick slices in a non-random region-of-interest (ROI) spatially identified by $^3$He MRI to contain ventilation defects. In order to spatially register CT and $^3$He MRI breath-hold volumes and anatomy, CT was acquired similar to MRI with subjects in breath-hold after inhalation of 1.0L of N$_2$ from FRC.

Image Analysis: $^3$He MRI semi-automated segmentation was performed using custom software generated using MATLAB R2007b, as previously described (2). Briefly, $^3$He MRI was segmented using a K-means approach that classified voxel intensity values into five clusters ranging from signal void (cluster 1, CI or ventilation defect volume (VDV)) to hyper-intense signal (cluster 3), generating a $^3$He voxel cluster-map. For delineation of the ventilation defects from the thoracic cavity, the $^3$He MRI thoracic cavity was segmented and $^3$He ventilation defect percent (VDP) was generated using VDVs normalized to the thoracic cavity volume (TCV). This software enabled the segmentation of whole lung (WL) VDP as well as VDP in the ROI corresponding to the regional CT Volume. The regional CT volume and $^3$He MRI were co-registered to quantify VDP and CT-derived airway measurements in the same anatomical region. Thoracic CT images were evaluated using commercial automated segmentation software (VIDA Diagnostics). Wall area percentage (WA%) and lumen area (LA) were quantified for the segmental bronchi within the regional CT volume. For each subject all airway segment measurements were averaged for the right and left lung separately to report whole lung averages. Either the right or left lung was evaluated based on the ability of the software to delineate and segment airways in the CT ROI. In the case where both lungs were evaluable, the lung side selection was randomized so that in total there were 9 left and 9 right asthmatic lungs (all from different subjects) as well as 3 left and 2 right healthy lungs.

Statistical Analysis: A multivariate analysis of variance (MANOVA) was performed using SPSS 20.0 (IBM, Armonk, NY, USA). Linear regression ($r^2$) and Pearson correlation coefficients (r) were used to determine the relationship between CT and $^3$He MRI measurements using GraphPad Prism version 4.00 (GraphPad Software Inc, San Diego, CA, USA). Results were considered statistically significant when the probability of making a Type I error was less than 5% (p < 0.05).

Results: Subject characteristics and imaging measurements are provided in Table 1 for 18 asthmatics and 5 healthy subjects. Figure 1 shows the hyperpolarized $^3$He MRI static ventilation image and the regional CT of the central coronal slice including regional measurements for WA%, LA and VDP for a healthy volunteer and two asthmatic subjects. As shown in Table 1, CT-derived measurements of regional WA% (p=0.009) and LA (p=0.01) were significantly different between asthmatics and healthy volunteers. Whole lung VDP (p=0.01) and regional VDP (p=0.02) were also significantly different between asthmatics and healthy volunteers. As shown in Figure 2, regional VDP was significantly correlated with WA% (r=0.48, p<0.001) (A) and LA (r=-0.51, r^2=0.26, p<0.01) (B). Dotted lines represent the 95% confidence intervals of the regression line.

Discussion: Taken together, these results suggest that there is a spatial structure-function relationship between airway morphological changes and ventilation defects, providing a better understanding of the underlying airway morphology related to heterogeneous ventilation abnormalities in asthma.

Conclusions: In a small group of asthmatic and healthy subjects, regional pulmonary CT measurements and airway wall thickness and lumen area were related to regional $^3$He MRI ventilation defects.

Figure 1. Regional hyperpolarized $^3$He MRI and CT for a healthy and asthmatic subject. The white box on the central coronal $^3$He static ventilation image shows the spatially registering CT-delineated ROI with the central coronal regional CT shown below. The lung side selected for analysis is highlighted in blue with the corresponding $^3$He and CT airway measurements shown below.

Figure 2. Relationship between regional $^3$He MRI ventilation defect measurements and CT airway measurements for all subjects. Regional VDP was significantly correlated with WA% (r = 0.48, r^2=0.23, p<0.02) (A) and LA (r = -0.51, r^2=0.26, p<0.01) (B). Dotted lines represent the 95% confidence intervals of the regression line.
