**Introduction:** Quantitative assessment of alveolar oxygen partial pressure ( $p_{\text{A}}\text{O}_2$ ) in the lung has the potential to become a remarkably useful tool in the diagnosis and monitoring of respiratory disease. Previously, quantification of  $p_{\text{A}}\text{O}_2$  has been demonstrated, both in vivo and in vitro, through the study of oxygen's effect on the spin-lattice relaxation time,  $T_1$ , of hyperpolarized  $^3\text{He}$  [1]. However, this approach requires careful calibration of the RF pulses, and can be time consuming. More recently, it has been demonstrated that  $p_{\text{A}}\text{O}_2$  can be measured using the spin-spin relaxation time,  $T_2$ , of  $^3\text{He}$  at very low magnetic field strengths [2] where the contribution of susceptibility-induced relaxation is insignificant.  $T_2$  can be measured with the Carr-Purcell-Meiboom-Gill (CPMG) sequence which has the inherent advantage of being able to reduce experiment time, increase experiment accuracy, and eliminate the need for extremely precise flip angle calibrations. To our knowledge, CPMG has not been applied to hyperpolarized  $^{129}\text{Xe}$  measurement of  $p_{\text{A}}\text{O}_2$  at low fields.  $^{129}\text{Xe}$  has the advantage of being highly abundant (i.e. inexpensive) compared to  $^3\text{He}$  and therefore may permit widespread use of the technique. We explore further the use of CPMG measurements for the determination of alveolar oxygen partial pressure using both hyperpolarized  $^3\text{He}$  and  $^{129}\text{Xe}$  gases in phantoms and in vivo in rat lung at low magnetic field (0.07T). We present relaxivity relationships for oxygen's effect on  $^3\text{He}$  and  $^{129}\text{Xe}$  spin-spin relaxation, and test the assertion that  $T_2=T_1$  in the limit of rapid CPMG pulse rates at low magnetic field strength [2,3].

**Methods:** Hyperpolarized  $^3\text{He}$  gas was produced using a turn-key polarizer (HeliSpin, GEHC). Hyperpolarized  $^{129}\text{Xe}$  gas was produced using a home-built spin exchange optical pumping system [4]. Plastic syringes were prepared with varying amounts of pure  $\text{O}_2$  gas and the remaining volume filled with hyperpolarized gas just prior to signal acquisition. NMR experiments were performed on a home-built resistive MR imaging system [5] at a field strength of 0.07T, and controlled using an Apollo console (TecMag, Houston, TX, USA). In vivo spin-spin relaxation times were measured using  $^3\text{He}$  gas in a 364g Sprague-Dawley rat ventilated with a custom ventilation system and a known  $p_{\text{A}}\text{O}_2$  of  $\sim 11\%$  using a University-approved animal care protocol. A CPMG pulse sequence [6] with an inter-echo time of 2.64ms and 8192 echoes was used to measure  $T_2$  for varying concentrations of  $\text{O}_2$  in vitro, and in vivo. Polarizations at the time of initial signal acquisition were estimated to be 25-30% for  $^3\text{He}$  and 5-10% for  $^{129}\text{Xe}$ . Total experiment time was 20-25 seconds.  $T_2$  was determined from the exponential decay of the echo amplitudes using a non-linear least squares fit.

**Results and Discussion:** The decay time measured by the CPMG sequence ( $T_{2,\text{CPMG}}$ ) can be broken down into constituent decay mechanisms according to:  $1/T_{2,\text{CPMG}} = 1/T_2 + 1/T_{2,\text{diff}}$  [2], where  $T_2$  is the true transverse relaxation time, which is assumed to be dominated by dipolar coupling with paramagnetic oxygen [3], and  $T_{2,\text{diff}}$  is the decay due to diffusion through magnetic field non-uniformities (principally susceptibility in the lung). Though low magnetic field reduces the diffusion term, it can still be significant due to the high diffusivity of gases. Therefore, we derive a linear relationship of the form:  $1/T_{2,\text{CPMG}} = \kappa P_{\text{O}_2} + \chi$  for both  $^3\text{He}$  and  $^{129}\text{Xe}$  (Fig.1), where the y-intercept  $\chi$  is proportional to the effect of diffusion on our measurements;  $\kappa$  is the slope of our linear fit; and  $P_{\text{O}_2}$  is the oxygen partial pressure in Pascals. The slope,  $\kappa$ , is calculated as  $5.80 \times 10^{-6} \text{ s}^{-1} \text{ Pa}^{-1}$  for  $^3\text{He}$  and  $4.20 \times 10^{-6} \text{ s}^{-1} \text{ Pa}^{-1}$  for  $^{129}\text{Xe}$ . A spin-spin relaxation time of  $22.6 \pm 1.6\text{s}$  was measured in vivo in the rat lung for  $^3\text{He}$ . A lengthening of the measured  $T_{2,\text{CPMG}}$  in vivo compared to phantom studies is seen and is attributed to the limited diffusion of the  $^3\text{He}$  gas within the lung. This value is equal, within experimental uncertainty, to the spin-lattice relaxation time measured previously for  $^3\text{He}$  under comparable ventilation conditions [1], demonstrating the feasibility of performing  $p_{\text{A}}\text{O}_2$  measurements of

the lung in vivo using measurements of low field  $T_2$  of  $^3\text{He}$  or  $^{129}\text{Xe}$  in the lung. This also supports the assertion that when diffusion induced relaxation through susceptibilities becomes negligible using a combination of low field and fast CPMG, a regime in which  $T_2=T_1$  is reached.

**Conclusions:** We have presented a method of measuring oxygen partial pressure at low fields with hyperpolarized gases using spin-spin relaxation times in vitro obtained with CPMG. We obtain a linear relationship between  $1/T_{2,\text{CPMG}}$  and the oxygen partial pressure, with values of  $5.80 \times 10^{-6} \text{ s}^{-1} \text{ Pa}^{-1}$  and  $4.20 \times 10^{-6} \text{ s}^{-1} \text{ Pa}^{-1}$  for the relaxivity of  $^3\text{He}$  and  $^{129}\text{Xe}$  in the presence of  $\text{O}_2$ , respectively.  $\kappa$  for  $^3\text{He}$  is greater than that for  $^{129}\text{Xe}$ , however the low cost of using  $^{129}\text{Xe}$  in experiment makes it a more desirable candidate for  $p_{\text{A}}\text{O}_2$  measurement in the future. A  $T_2$  of  $2.6 \pm 1.6\text{s}$  was also measured using  $^3\text{He}$  in rat lung.

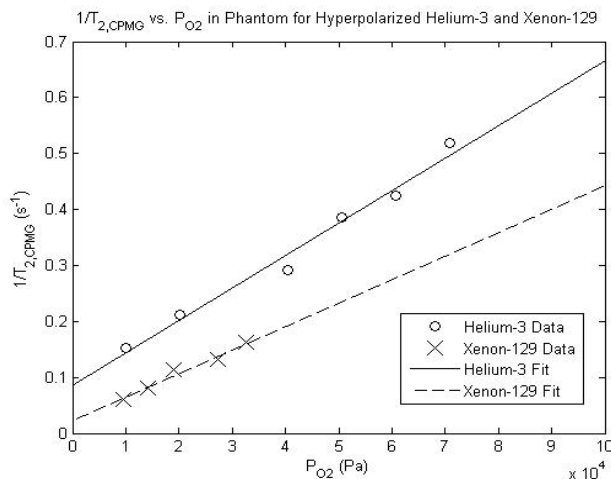

Figure 1.  $1/T_{2,\text{CPMG}}$  vs.  $P_{\text{O}_2}$  for  $^3\text{He}$  and  $^{129}\text{Xe}$
