Introduction

Previously we showed that the use of long echo times (TE) in ¹H-MRS gives the opportunity to measure acetylcarnitine concentrations at rest on a 3T human MR scanner, which is available at most clinical research sites nowadays (1). This is highly interesting in the light of recent research, where whole body carnitine diminution is linked to insulin resistance and metabolic inflexibility (2). Here, we investigated skeletal muscle acetylcarnitine content in four groups, known to differ in insulin sensitivity and metabolic health.

Methods

The groups investigated comprised of type 2 diabetic patients (T2DM, N = 9), obese sedentary (OB, N = 10), lean sedentary (UT, N = 9) and endurance trained (T, N = 12) subjects. All participants were asked to remain fasted for 5 hours prior to the measurement. ¹H-MRS was performed using a 3.0 T whole body MRI-scanner (Achieva 3T-X, Philips Healthcare, Best, The Netherlands). The subjects were positioned supine in the magnet bore, with the left leg parallel to the main magnetic field and with the foot constrained by two sandbags. A two-element flexible surface coil was placed over the vastus lateralis muscle. A PRESS (3) sequence was used for volume selection and outer volume suppression was applied to eliminate residual signals of subcutaneous adipose tissue. The voxel was placed in the vastus lateralis muscle and spectra were acquired with the following acquisition parameters: TR = 6000 ms, TE = 350 ms, spectral bandwidth = 2 kHz, number of acquired data points = 2048, number of averages (NSA) = 20, phase cycling steps = 4. Shimming was performed with standard pencil beam shimming. Voxel dimensions were 40 mm x 20 mm x 60 mm, resulting in a large volume of 48 mL. The acetylcarnitine concentration was calculated, using the total creatine (t-Cr) resonance as internal reference. Both mm, resulting in a large volume of 48 mL. The acetylcarnitine concentration was calculated, using the total creatine (t-Cr) resonance as internal reference. Both metabolites were T₂ corrected. A hyperinsulinemic-euglycemic clamp was performed to measure insulin sensitivity (given as glucose infusion rate (GIR)). Additionally, ³¹P-MRS was used to measure phosphocreatine (PCr) recovery rate, as a measure of in vivo mitochondrial function. A one-way ANOVA test, with post-hoc Bonferroni correction, was used for statistical analysis.

Results

Two representative spectra, acquired from an endurance trained athlete and a T2DM patient, respectively, are shown in figure 1. An overall difference in acetylcarnitine content across groups characterized by varying insulin sensitivity and metabolic health. The results may indicate that T2DM subjects have a lower ability to form acetylcarnitine, possibly underlying a decreased insulin sensitivity and metabolic flexibility.

Discussion

Our results show differences in acetylcarnitine content across groups characterized by varying insulin sensitivity and metabolic health. The results may indicate that T2DM subjects have a lower ability to form acetylcarnitine, possibly underlying a decreased insulin sensitivity and metabolic flexibility.
